CHAPTER 10: APPLICATIONS

An Introduction to Multiagent Systems

http://www.csc.liv.ac.uk/~mjw/pubs/imas/

1 Application Areas

- Agents are indicated for domains where autonomous action is required
- Multiagent systems are indicated for domains where:
- control, data, expertise are distributed;
- centralised control is impossible or impractical;
- processing nodes have competing/conflicting viewpoints or objectives

Some Applications

- Interface agents;
- Internet agents,
- E-commerce agents,

1.1 Interface Agents

- The idea is to move away from the direct manipulation paradigm that has dominated for so long.
- Agents sit 'over' applications, watching, learning, and the initiative. eventually doing things without being told — taking
- Pioneering work at MIT Media Lab (Pattie Maes):
- news reader;
- web browsers;
- mail readers.

Nicholas Negroponte's Vision

trained in timing, versed in finding opportune moments, and respectful of appropriate, and may even tell a white lie on your behalf. The same agent is well 'The 'agent' answers the phone, recognises the callers, disturbs you when idiosyncracies. ' (p150)

using it in your best interests.' (p151) Einstein. This issue is not about IQ. It is shared knowledge and the practice of falls ill, it would make no difference if the temping agency could send you Albert 'If you have somebody who knows you well and shares much of your information, that person can act on your behalf very effectively. If your secretary

desires.' (p158) multiplies. But [this process] started at the interface where you delegated your collect information on your behalf. Agents will dispatch agents. The process 'Like an army commander sending a scout ahead ... you will dispatch agents to

(From Being Digital, 1995.)

2 Email Reading Assistants

- MAXIMS (Pattie Maes, 1994) 'learns to prioritize, behalf of a user ... delete, forward, sort, and archive mail messages on
- Works by 'looking over the shoulder' of a user, and learning about how they deal with email.
- Each time a new event occurs (e.g., email arrives), generated MAXIMS records the situation → action pairs
- Situation characterised by features of event:

sender of email; recipients; subject line; etc.

When new situation occurs, MAXIMS matches it against previousy recorded rules.

- Predicts user action, and generates a confidence level
- Confidence level compared against two threshholds: "tell me" and "do it":

confidence < "tell me"

agent gets feedback

"tell me" < confidence < "do it"

agent makes suggestion

confidence > "do it":

agent acts

Rules can be "hard coded"; even get help from other users

MAXIMS has a simple 'personality', (a face icon), communicating its 'mental state' to the user.

3 Agents on the Internet

- It is not easy to find the right information (even with the help of search engines).
- Systematic searches are difficult:
- human factors: we get bored by slow response get tired, miss things easily, misunderstand, get times, find it difficult to read the WWW rigorously, sidetracked;
- organizational factors: structure on the net is superficial — no standards for home pages, not contains; (yet) semantic markup to tell you what a page

The sheer amount of information presented to us leads to 'information overload'.

- What we want is a kind of 'secretary': someone who things we are not interested in), who can act as 'proxy', hiding information that we are not interested understood the things we were interested in, (and the **Interest** in, and bringing to our attention information that is of
- We cannot afford human agents to do these kinds of drawbacks we mentioned above). tasks (and in any case, humans get suffer from the
- So we write an agent to do these tasks.

Tour guides

- The idea here is to have agents that help to answer **₩** the question 'where do I go next' when browsing the
- Such agents can learn about the user's preferences in the same way that MAXIMS does, and rather than just providing a single, uniform type of hyperlink actually indicate the likely interest of a link

Indexing agents

- abstraction on top of the services provided by Indexing agents will provide an extra layer of search/indexing agents such as GOOGLE and LYCOS.
- The idea is to use the raw information provided by goals, preferences, etc., to provide a personalised such engines, together with knowledge of the users service

FAQ-finders

- The idea here is to direct users to FAQ documents in order to answer specific questions.
- Since FAQS tend to be knowledge intensive, structured FAQ servers. documents, there is a lot of potential for automated

Expertise finders

- Suppose I want to know about experts in intelligent agents
- Current WWW search tools would simply take the words "intelligent" "agents" and search on them.
- This is not ideal: GOOGLE has no model of what you mean by this search, or what you really want.
- Expertise finders 'try to understand the users wants provide a better information provision service and the contents of information services', in order to

4 Agents for E-Commerce

- Another important rationale for internet agents is the potential for *electronic commerce*.
- Most commerce is currently done *manually*. But there commerce could not be safely delegated to agents. is no reason to suppose that certain forms of
- Examples:
- find the cheapest copy of MS Office from online stores;
- flight from Manchester to Dusseldorf with veggie restaurants meal, window seat, plus hotel, taxis, entertainment,

First & Second Generation E-Commerce Systems

- First generation: comparison shopping agents.
- Examples:
- 1995: Bargain Finder from Andersen;
- 1997: Jango from NETBOT.
- 2003: Froogle from GOOGLE
- Second-generation: negotiation, brokering, ...

Jango

- Jango (Doorenbos et al, Agents 97) is good example of e-commerce agent.
- Long-term goals:
- 1. Help user decide what to buy.
- 2. Finding specs and reviews of products.
- 3. Make recommendations.
- 4. Comparison shopping for best buy.
- 5. Monitoring "what's new" lists
- 6. Watching for special offers & discounts.

- Isn't comparison shopping impossible? WWW pages all different!
- Jango/ShopBot exploits several regularities in merchant WWW sites:
- corporate regularity navigation regularity. sites designed so that products easy to find
- sites designed so that pages have same look'n'feel;
- vertical separation: merchants use whitespace to separate products

- Two key components of Jango/ShopBot:
- learning vendor descriptions;
- comparison shopping;
